

Induction Heating as Efficient Heating Technology in Manufacturing

John Pham

Current State

Greenhouse gas emissions by sector, World

Our World
in Data

Emissions are measured in carbon dioxide equivalents (CO₂eq). This means non-CO₂ gases are weighted by the amount of warming they cause over a 100-year timescale.

Source: Our World in Data based on Climate Analysis Indicators Tool (CAIT).

Note: Greenhouse gases are weighted by their global warming potential value (GWP100). GWP100 measures the relative warming impact of one molecule of a greenhouse gas, relative to carbon dioxide, over 100 years.

Heat Transfer Limitations

1. Slow heating/cooling rate
2. Nonuniform heating environments
3. Low energy efficiency
4. Heat losses
 - Due to the prolonged exposure of reagents and products to large temperature gradients in the reactor

Heating Method

- Flame and resistance heating or furnaces
 - Heating scheme based on conduction/convection/radiation
 - Wall heated to conduct heat to the catalyst create large temperature gradients into the reactor → heat loss
- Induction heating
 - Reaches higher temperatures more quickly on the catalyst without heating catalyst support, liquid/gaseous carriers and reagents, or the entire reactor → save energy
 - Simple set up because it is noncontact
 - Highest power transmission because energy is transferred within the materials

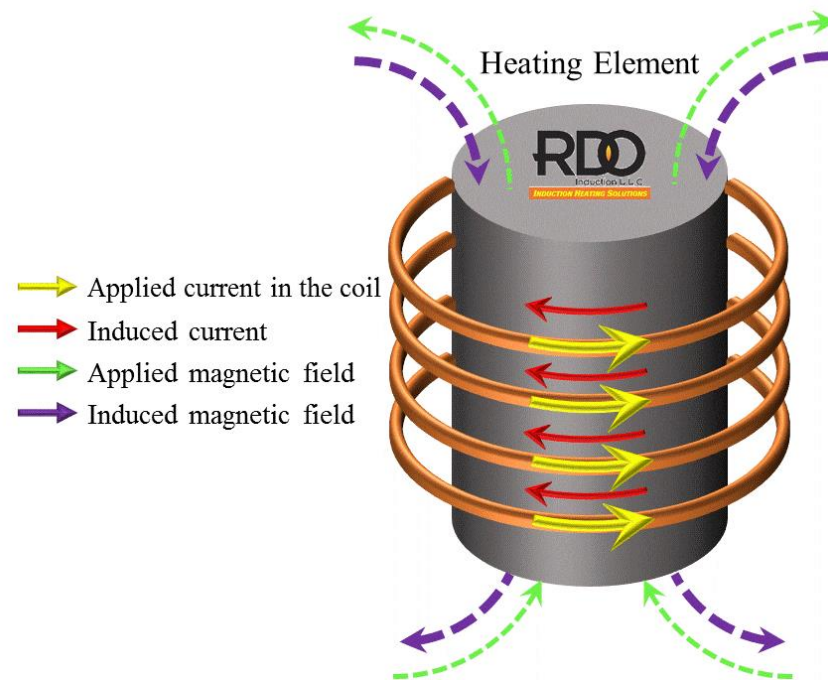

What is induction heating?

- Induction heating technology uses an AC source as a supplied power for the alternating voltage.
- The induction target is immersed in the induction coil and experiences the alternating magnetic field generated by the coil.

How does it work?

- Directly heats the susceptor by two physical phenomena:
 - Eddy currents
 - Magnetic hysteresis

Eddy Currents

- Heat is produced by the Joule effect in which eddy current creates the resistance to the magnetic field applied to the induction target.
- Concentrate in the susceptor surface
- Large particles

Hysteresis Loss

- As the direction of the magnetic field keeps changing and switching back and forth, the magnetic material absorbs energy during each line on the hysteresis loop and releases this energy as heat.
- Uniform
- Small particles

How induction heating
overcomes heat
transfer efficiency

Design A

Design A

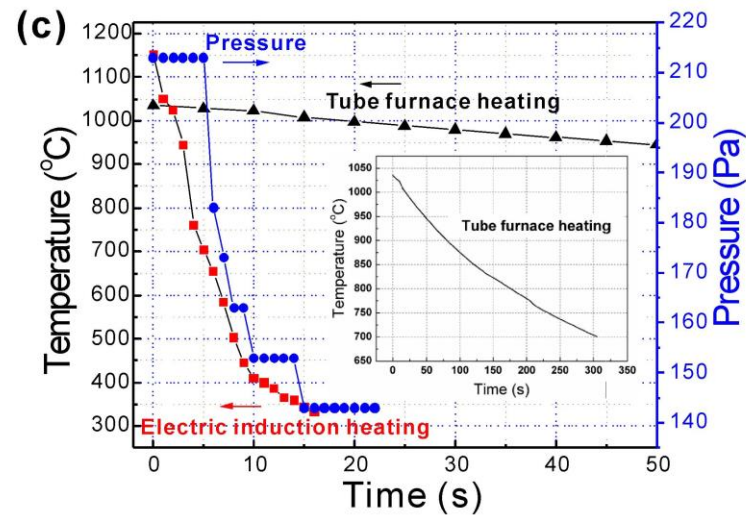

Faster heating/cooling rate

- “Cold wall” reactor
- Negligible thermal inertia
- No temperature gradients into the reactor

Reduce Heat Loss

- Do not waste heat on catalyst bed supports
 - Carrier gas
 - Reactor

Higher Efficiency

- Require less power to heat the catalyst bed
- Uniform temperature throughout the bed

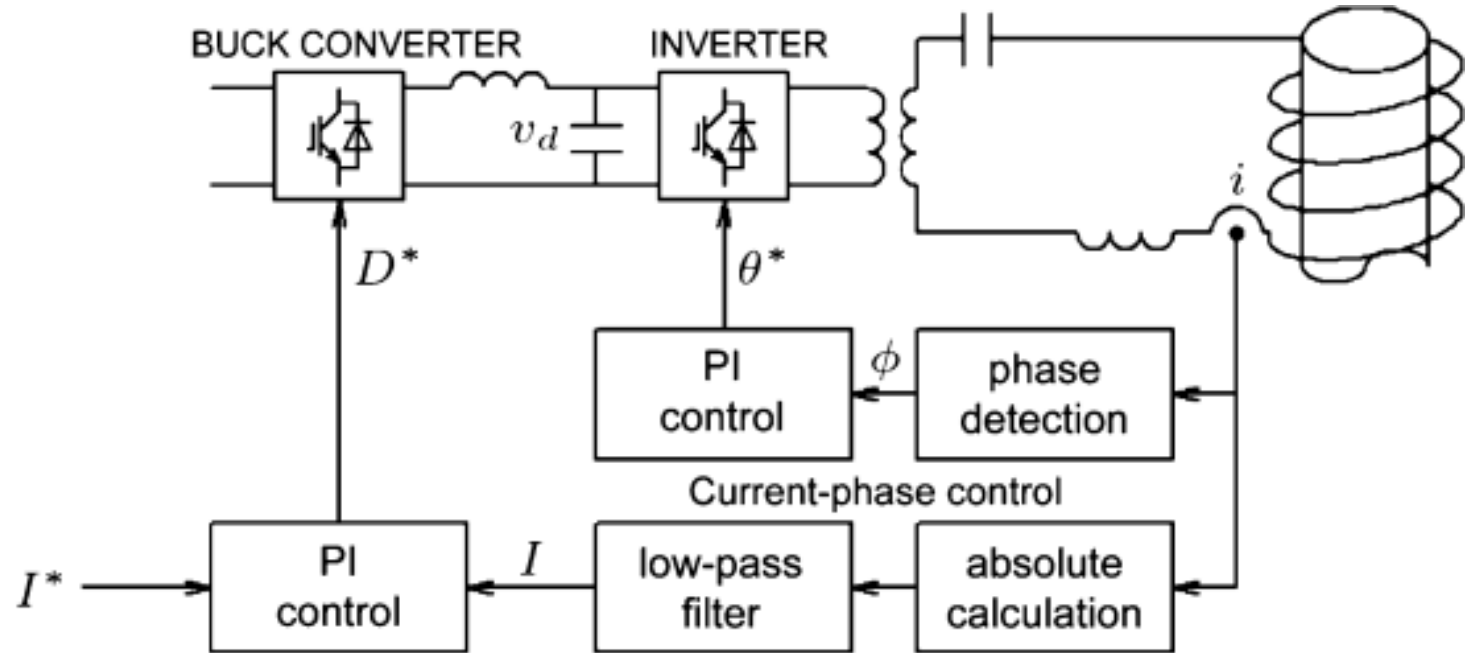

Type of Heating Element	Efficiency Factor
Electric - Induction	84.00%
Electric - Radiant*	71.00%
Gas	40.00%

Efficiency Chart Source: US Department of Energy (1998)

Safe and Precise Control

- Predetermined temperature profiles
- PI controllers can be utilized to ensure the elimination of waste energy
